How to detect intestinal worms

A Canadian doctor has produced a microscope that works reasonably well at diagnosing intestinal worms in children.

The invention, described recently in *The American Journal of Tropical Medicine and Hygiene*, was tested in Tanzania. A little \$8 lens was taped with a piece of double-sided tape over the lens of an iPhone 4. The camera's zoom was increased to maximum, and microscope slides were pressed right up to the lens, with another bit of tape atop the samples to keep the lens clean. A pen flashlight shone light through the slide.

The inexpensive arrangement did not match the accuracy of a scan of the same slides with a conventional microscope, but it did about 70 percent as well. The iPhone set-up correctly detected giant roundworm eggs 81 percent of the time and roundworm eggs 54 percent of the time. But it was only 14 percent accurate at finding hookworm eggs.
